Are youth really gaining more weight during the pandemic than in previous years?
If they are gaining more weight, are there differences by age?
Is the weight gain worse within communities of color that have been hardest hit by the pandemic and have a disproportionately high prevalence of excess weight?
What, if any, long-term impact will this weight gain have on health?
What interventions are needed to address this weight gain?
Pandemic timeline in California

California had one of the highest per capita rates of COVID-19 infection in the world.
Study design and population

**Retrospective Cohort**
School-aged youth (5–17 years old)

- Pre-Pandemic
  - March 2019
  - April
  - May
  - June
  - July
  - Aug
  - Sept
  - Oct
  - Nov
  - Dec
  - Jan 2020

- Pandemic Lockdown
  - March 2020
  - April
  - May
  - June
  - July
  - Aug
  - Sept
  - Oct
  - Nov
  - Dec
  - Jan 2021

≥ 1 BMI

No in-person visits

≥ 1 BMI
Source Population

KPSC members
5-17 years old on March 1, 2020
N = 1,275,578

Excluded:
- No continuous membership 24 months prior to March 2020 (N = 658,912)
- Complex chronic conditions (N = 47,316)

KPSC continuous membership
5-17 years old with no complex chronic conditions
N = 569,350

Eligible Cohort

No BMI between June 16, 2020 and Jan 31, 2021 (N = 371,643)

5-17 years old with 1+ BMI during COVID-19
N = 197,707

Analytical Cohort

No BMI before March 16, 2020 (N = 6,198)

5-17 years old with 1+ BMI during pandemic & 1+ BMI before pandemic
N = 191,509
Analytical Cohort

5-17 years old with 1+ BMI during pandemic & 1+ BMI before pandemic
N = 191,509

- Similar to KPSC youth in all covariates assessed: Age, sex, race/ethnicity, weight status, state-subsidized health insurance, neighborhood income, education, parks

- Diverse: Hispanic 50.4%
  Non-Hispanic White 25.3%
  Non-Hispanic Black 7.0%
  Asian/Pacific Islander 9.8%

- Total BMI measures - 425,855 before COVID-19 (2.22 BMI/youth) and 283,718 during COVID-19 (1.48 BMI/youth).
Statistical analysis

- Outcomes of the study were:
  - Distance from the median BMI for sex and age
  - Weight adjusted for height
  - Percent overweight or obese

- Mixed effect regression models accounting for repeated measures within child with an autoregressive correlation structure and maximum likelihood estimation of the covariance parameters – accommodates missing outcomes at some time points.

- Linear term best fit for the data (using AICC, BIC, and the likelihood ratio test)
  - But necessary to analyze three age strata (5-11, 12-15, 16-17 years) based on unadjusted penalized b-splines and visual assessment of the relationship of BMI and calendar month.

- Models adjusted for adjust for race/ethnicity, sex, neighborhood education and income, number of parks and state-subsidized insurance.

- BMI and body weight models were also adjusted for BMI-for-age group at baseline, and the model for body weight was further adjusted for height.
Primary Outcome: Distance from the median BMI-for-age

16-17 years old

$\Delta^2 - \Delta^1 = 0.48 \text{ kg/m}^2 \ (CI 0.41, 0.55)$

$2.26 \text{ lbs} \ (CI 1.87, 2.65)$

Pre-pandemic  Pandemic
Primary Outcome: Distance from the median BMI-for-age

12-15 years old

$\Delta 2 - \Delta 1 \quad 0.91 \text{ kg/m}^2 \ (CI \ 0.86, 0.96)$

$5.10 \text{ lbs} \ (CI \ 4.84, 5.37)$
Primary Outcome: Distance from the median BMI-for-age

5-11 years old

Δ2 – Δ1  1.57 kg/m² (CI 1.52, 1.62)
5.07 lbs    (CI 4.93, 5.21)
Secondary Outcome: Overweight and obesity

Comparison from NHANES: Annual increase in obesity 2000-2018: 0.2% in 6-11 yrs, 0.4% in 12-19 yrs

Increases in Children’s BMI Rate of Change during the COVID-19 Pandemic

Samantha Lange, MPH
Centers for Disease Control and Prevention

Disclaimer: The findings and conclusions in this presentation are those of the authors and do not necessarily represent the official position of the Centers for Disease Control and Prevention (CDC).
Longitudinal Cohort Definition

• Aim: to compare trends in children’s BMI before and during the pandemic
• Data Source: IQVIA Ambulatory Electronic Medical Record (AEMR) dataset
• Cohort: 432,302 children 2-19y with ≥3 BMI measurements

Note: BMIs taken during March – May 2020 were included in the analysis but not used to define cohort selection criteria.
Among 432,302 children in IQVIA-

- The monthly rate of BMI change nearly doubled during the pandemic (0.100 vs. 0.052 kg/m²; slope ratio: 1.93)
- Largest increases among-
  - Children with overweight or obesity
  - Children aged 6-11y

### Sharp Increases in Rates of BMI Change during Pandemic

</table>

Ongoing Analyses

• Reran with additional data
  • Pandemic period: June 2020-May 2021
  • Children in all BMI categories except underweight had significant increases in rates of BMI change
  • Attenuation in some effects

• Sub-analysis by sex
  • Higher rate of BMI change in males
Thank you!
